# Link layer: introduction

## *terminology:*

- ❖ hosts and routers: **nodes**
- ❖ communication channels that connect adjacent nodes along communication path: **links**
  - wired links
  - wireless links
  - LANs
- ❖ layer-2 packet: **frame**, encapsulates datagram

*data-link layer* has responsibility of transferring datagram from one node to *physically adjacent* node over a link

# Link layer: context

- ❖ datagram transferred by different link protocols over different links:
  - e.g., Ethernet on first link, frame relay on intermediate links, 802.11 on last link
- ❖ each link protocol provides different services
  - e.g., may or may not provide rdt over link

## *transportation analogy:*

- ❖ trip from Princeton to Lausanne
  - limo: Princeton to JFK
  - plane: JFK to Geneva
  - train: Geneva to Lausanne
- ❖ tourist = **datagram**
- ❖ transport segment = **communication link**
- ❖ transportation mode = **link layer protocol**
- ❖ travel agent = **routing algorithm**

# Link layer services

- ❖ *framing, link access:*

- encapsulate datagram into frame, adding header, trailer
- channel access if shared medium
- “MAC” addresses used in frame headers to identify source, dest
  - different from IP address!

- ❖ *reliable delivery between adjacent nodes*

- we learned how to do this already (chapter 3)!
- seldom used on low bit-error link (fiber, some twisted pair)
- wireless links: high error rates
  - *Q:* why both link-level and end-end reliability?

# Link layer services (more)

## ❖ *flow control:*

- pacing between adjacent sending and receiving nodes

## ❖ *error detection:*

- errors caused by signal attenuation, noise.
- receiver detects presence of errors:
  - signals sender for retransmission or drops frame

## ❖ *error correction:*

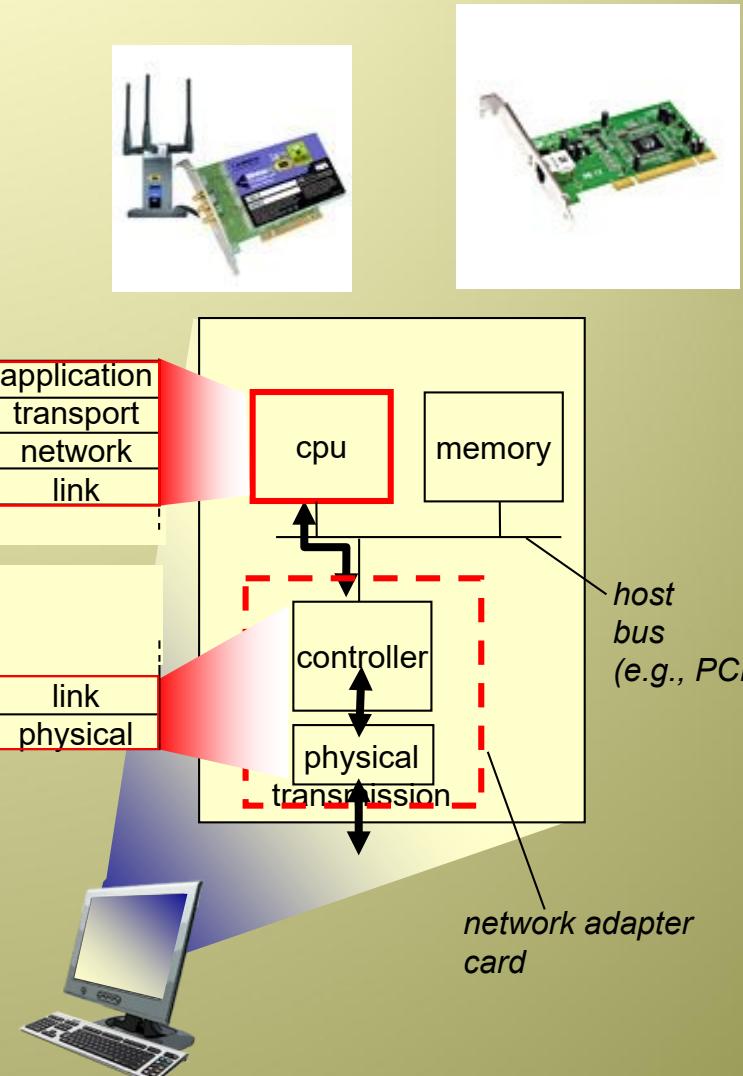

- receiver identifies *and corrects* bit error(s) without resorting to retransmission

## ❖ *half-duplex and full-duplex*

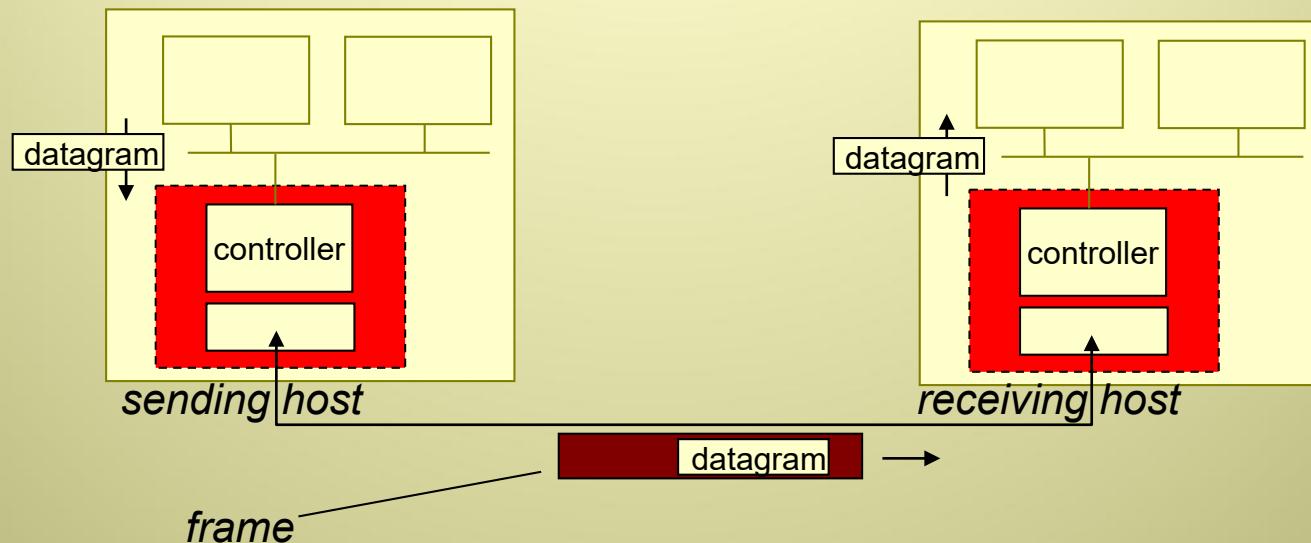

- with half duplex, nodes at both ends of link can transmit, but not at same time

# Where is the link layer implemented?

- ❖ in each and every host
- ❖ link layer implemented in “adaptor” (aka *network interface card* NIC) or on a chip
  - Ethernet card, 802.11 card; Ethernet chipset
  - implements link, physical layer
- ❖ attaches into host’s system buses
- ❖ combination of hardware, software, firmware

# Adaptors communicating

- ❖ **sending side:**
  - encapsulates datagram in frame
  - adds error checking bits, rdt, flow control, etc.
- ❖ **receiving side**
  - looks for errors, rdt, flow control, etc
  - extracts datagram, passes to upper layer at receiving side

# Data Integrity

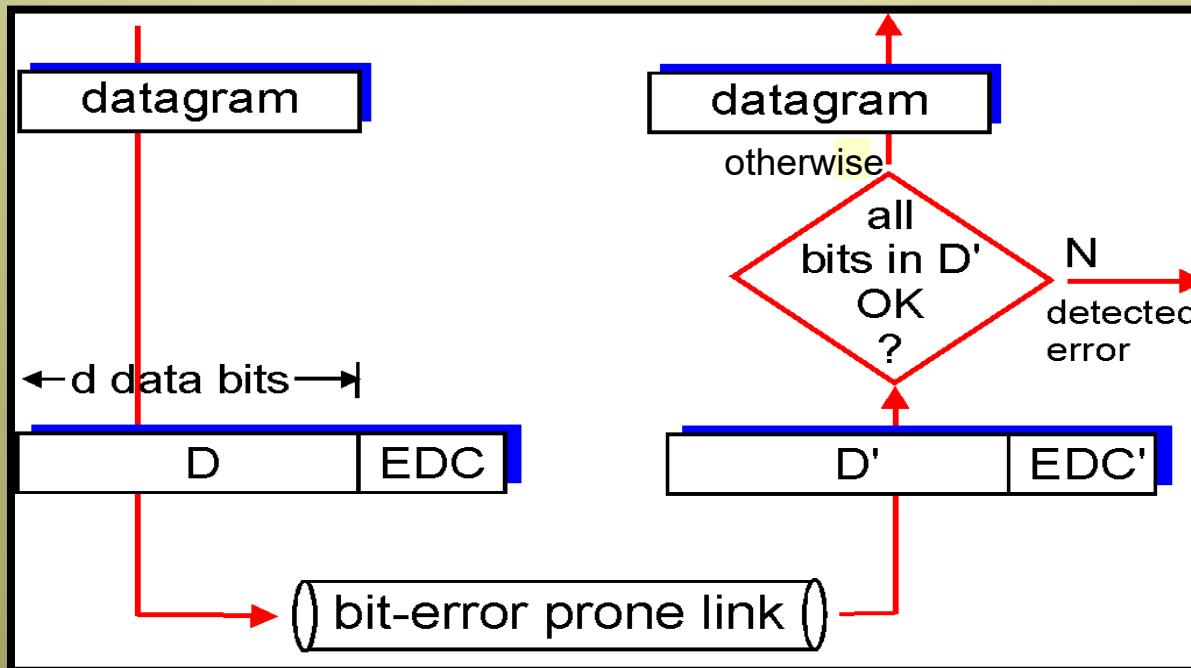

- ❖ *a possible reality:*  
*Data transferred → data altered → data received*
- ❖ *electrical interference, power fluctuation, sunspots, storms, ...etc. are all factors*
- ❖ **error detection** is hence needed
- ❖ *what can be done if errors are detected?*
- ❖ **error correction** may sometimes be the most suitable solution

# Error detection

EDC = Error Detection and Correction bits (redundancy)

D = Data protected by error checking, may include header fields

- Error detection not 100% reliable!
  - protocol may miss some errors, but rarely
  - larger EDC field yields better detection and correction

# Parity checking

- ❖ *simple/naïve*
- ❖ *send additional bits along with data*
- ❖ *the value of those additional bits depend on the data itself*
- ❖ *theoretically, if data is alerted, the value of the additional bits will no longer correspond to the new data*

# Parity checking

*Single-bit parity:*

- ❖ detect single bit errors
- ❖ parity checking – **even parity & odd parity**
- ❖ one **parity bit** is added to achieve that

data bits  
11010100 0

Parity bit is 0 to make the total number of 1s even.

data bits  
01101101 1

Parity bit is 1 to make the total number of 1s even.

Detecting Single-bit Errors Using Even Parity Checking

# Parity checking

- ❖ how many errors can a parity check detect?

- ❖ Examples: Assume the use of even parity

Sent: 10100010 **1** → Received: 1010**1**010 **1**

Sent: 10011110 **1** → Received: 10**10**1110 **1**

Sent: 10001110 **0** → Received: 1**111**1110 **0**

Sent: 10001110 **0** → Received: 1**111**1110 **1**

≡ Errors detected

≡ No errors detected

*Notice that all the above examples do have errors!*

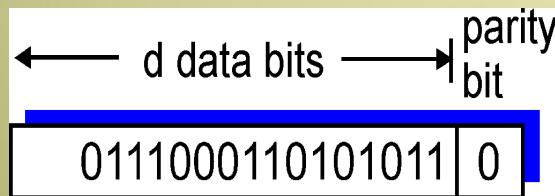

# Parity checking

- ❖ in reality, single-bit errors are rare
- ❖ an error for a duration of  $1/100$  second over a 10Mbps line may affect 10,000 bits
- ❖ when many bits are damaged, we refer to that as ***burst errors***
- ❖ in average, parity check would catch about 50% of burst errors
- ❖ in other words, it is 50% accurate, which is simply not good for communications networks
- ❖ this however does not mean that parity checking is useless.  
Why?

# Parity checking

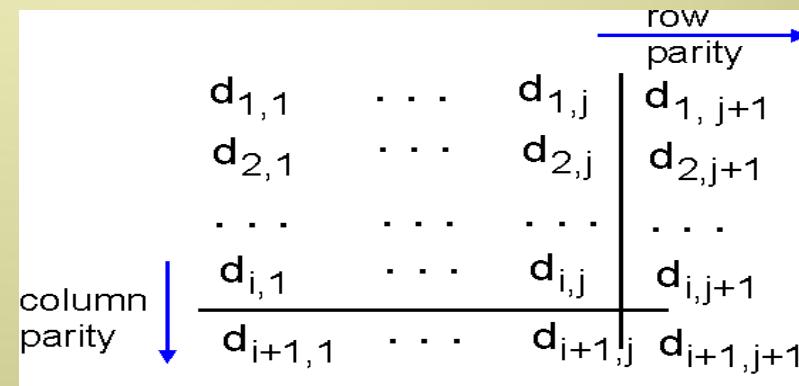

## *single bit parity:*

- ❖ detect single bit errors

## *two-dimensional bit parity:*

- ❖ detect and correct single bit errors

101011  
111100  
011101  
001010

*no errors*

101011  
101100  
011101  
001010

parity error  
parity error

*correctable  
single bit error*

# Checksum

- ❖ divide all data bits into groups (i.e. 32-bit groups)
- ❖ treat each group as an integer value
- ❖ the values are then added together to give a **checksum**
- ❖ the checksum is then appended to the sent data and tested at the receiving end
- ❖ more accurate than parity checking, however it may not detect all errors. Why?

# Internet checksum (review)

**goal:** detect “errors” (e.g., flipped bits) in transmitted packet  
(note: used at transport layer only)

## **sender:**

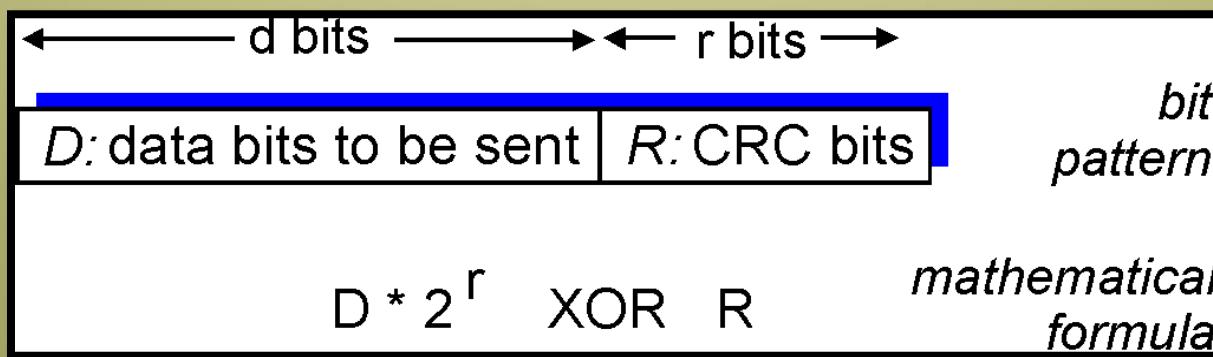

- ❖ treat segment contents as sequence of 16-bit integers
- ❖ checksum: addition (1's complement sum) of segment contents
- ❖ sender puts checksum value into UDP checksum field

## **receiver:**

- ❖ compute checksum of received segment
- ❖ check if computed checksum equals checksum field value:
  - NO - error detected
  - YES - no error detected.  
*But maybe errors nonetheless?*

# Cyclic Redundancy Check (CRC)

- ❖ more powerful error-detection coding
- ❖ view data bits, **D**, as a binary number
- ❖ choose bit pattern (generator), **G**
  
- ❖ goal: choose CRC bits, **R**, such that
  - $\langle D, R \rangle$  exactly divisible by G (modulo 2)
  - receiver knows G, divides received  $\langle D, R \rangle$  by G. If non-zero remainder: error detected!
  
- ❖ widely used in practice (Ethernet, 802.11 WiFi, ATM)

# Cyclic Redundancy Check (CRC)

## Cyclic Redundancy Checks (CRC) - Details

- ❖ errors are detected via ***polynomial division***
- ❖ in general, a polynomial interpretation is made for any bit string
- ❖ for example, the bit string

$$b_{n-1}b_{n-2}b_{n-3}\dots b_2b_1b_0$$

is interpreted as the polynomial

$$b_{n-1}x^{n-1} + b_{n-2}x^{n-2} + b_{n-3}x^{n-3} + \dots + b_2x^2 + b_1x + b_0$$

- ❖ since each bit here is either 0 or 1, we can consider  $x^i$  only when  $b=1$
- ❖ for example, the bit string **1001010110**  
is interpreted as

$$x^{10} + x^7 + x^5 + x^3 + x^2 + x^1$$

# Cyclic Redundancy Check (CRC)

## **Cyclic Redundancy Checks (CRC) - Polynomial Division**

- ❖ Modulo 2 addition and subtraction (Ex-Or arithmetic) are as follows:

**Addition:**  $0+0=0$ ;  $1+0=1$ ;  $0+1=1$ ;  $1+1=0$

**Subtraction:**  $0-0=0$ ;  $1-0=1$ ;  $0-1=1$ ;  $1-1=0$

- ❖ Assume  $T(x)$  and  $G(x)$  are two polynomials as follows:

$$T(x) = x^{10} + x^9 + x^7 + x^5 + x^4$$

$$G(x) = x^4 + x^3 + x^0$$

- ❖ What is  $T(x)/G(x)$ ?

# Cyclic Redundancy Check (CRC)

## Cyclic Redundancy Checks (CRC) - Polynomial Division

What is  $T(x)/G(x)$ ?

$$\begin{array}{r} & x^6 & + x^3 & + x \\ \hline x^4 + x^3 + 1 & ) & x^{10} + x^9 & + x^7 & + x^5 + x^4 \\ & x^{10} & + x^9 & & + x^6 \\ \hline & & & x^7 & + x^6 + x^5 + x^4 \\ & & & x^7 & + x^6 & + x^3 \\ \hline & & & x^5 & + x^4 & + x^3 \\ & & & x^5 & + x^4 & + x \\ \hline & & & x^3 & + x & \text{remainder} \end{array}$$

Calculation of  $(x^{10} + x^9 + x^7 + x^5 + x^4) / (x^4 + x^3 + 1)$

# Cyclic Redundancy Check (CRC)

## Cyclic Redundancy Checks (CRC) - Polynomial Division

The equivalent synthetic division of  $T(x)/G(x)$  would look as follow

Synthetic Division of  
 $(x^{10} + x^9 + x^7 + x^5 + x^4)/(x^4 + x^3 + 1)$

A synthetic division diagram showing the division of  $T(x) = x^{10} + x^9 + x^7 + x^5 + x^4$  by  $G(x) = x^4 + x^3 + 1$ . The dividend is represented by the binary number 1001010, and the divisor is 11001. The quotient is 10010 and the remainder is 1010.

# Cyclic Redundancy Check (CRC)

## Cyclic Redundancy Checks (CRC)

- ❖ How does CRC work?
  - Given a bit string, append several 0s to it, and call be  $B$
  - Find the polynomial interpretation of  $B$ ; that is  $B(x)$
  - Agree on some polynomial value  $G(x)$  (called **generator polynomial**)
  - Divide  $B(x)/G(x)$  and find the remainder polynomial  $R(x)$
  - Define  $T(x) = B(x) - R(x)$
  - Find the bit string of  $T(x)$ ; call it  $T$
  - Transmit  $T$
  - Let  $T'$  is the received string
  - Divide  $T'(x)/G(x)$
  - → if there is a zero remainder then  $T = T'$ , which means no errors
  - Otherwise, errors are detected

# Cyclic Redundancy Check (CRC)

- ❖ Example: Suppose the bit string 1101011 is to be sent
  - Assume  $G(x) = x^4 + x^3 + 1$
  - Append four 0s at the end of the string  $\rightarrow B = 11010110000$
  - $B(x) = x^{10} + x^9 + x^7 + x^5 + x^4$
  - $B(x)/G(x) \rightarrow$  The remainder  $R(x) = x^3 + x$
  - $T(x) = B(x) - R(x)$ ; this can be done by subtracting over the bit strings  
 $11010110000$  bit string B  
- $1010$  bit string R  
 $11010111010$  bit string T (*Notice that  $T(x)/G(x)$  has a zero remainder*)

In algebra the following analogy is true: If  $p$  and  $q$  are integers and  $r$  is the remainder of  $p/q$ , then  $p-r$  is evenly divisible by  $q$ . for example,  $8/3$  generates a remainder of 2.  $8-2$  is evenly divisible by 3.

# Cyclic Redundancy Check (CRC)

## Cyclic Redundancy Checks (CRC)

- ❖ Example (continues...):

Dividing  $T(x)/G(x)$

The diagram shows the division of the dividend  $1001010$  by the divisor  $11001$ . The quotient is  $10010$  and the remainder is  $0000$ . Blue arrows point from the divisor to each step of the subtraction process.

# Cyclic Redundancy Check (CRC)

## Cyclic Redundancy Checks (CRC)

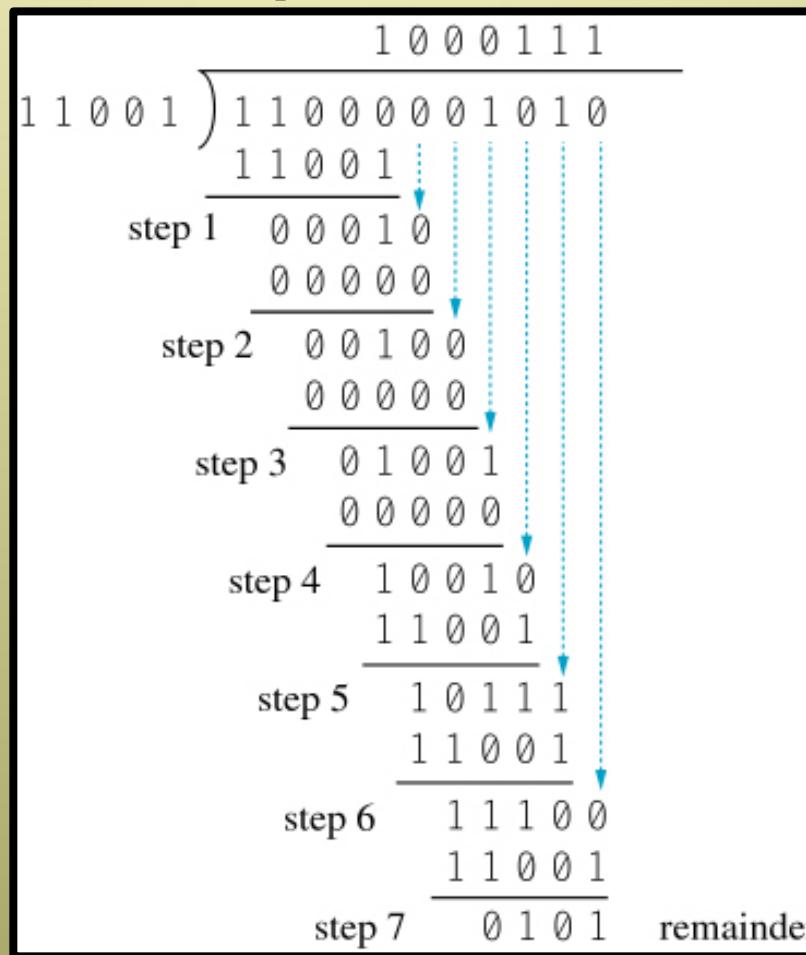

- ❖ Example (continues...):
  - *Transmit  $T$*
  - *Let  $T'$  is the received string*
  - *Divide  $T'(x)/G(x)$*
  - **→ if there is a zero remainder then  $T = T'$ , which means no errors**
  - *Otherwise, errors are detected*
  - *Notes: In practice the following holds true:*
    - *A non-zero remainder concludes that errors have occurred*
    - *A zero remainder however is not that conclusive. Unless  $G(x)$  is chosen carefully, it is possible that a damaged  $T'$  may still result in a zero remainder when  $T'(x)$  is divided by  $G(x)$*

# Cyclic Redundancy Check (CRC)

## CRC Implementation Using Circular Shifts

- ❖ Performing CRC check for each data arrival is a massive overhead
- ❖ How fast can the polynomial division be performed? Does it have to be complete?

Dividing  $T(x)/G(x)$   
When Error Occurs

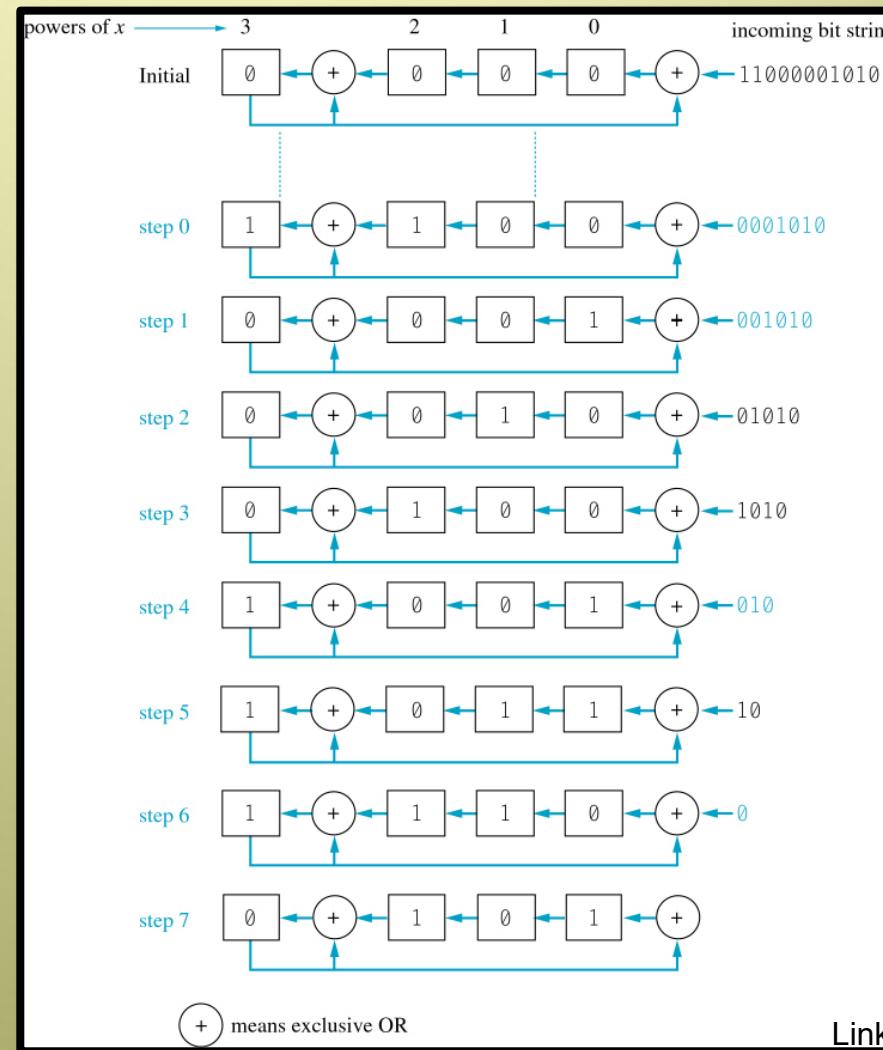

# Cyclic Redundancy Check (CRC)

## CRC Implementation Using Circular Shifts

- division using circular shifts

Dividing  $T(x)/G(x)$   
Using Circular Shift

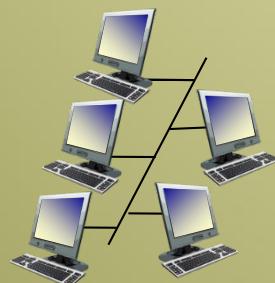

[ $G(x) = x^4 + x^3 + 1$   
& hardware has 4 registers]

# Multiple access links, protocols

two types of “links”:

- ❖ **point-to-point**
  - i.e. point-to-point link between Ethernet switch, host
- ❖ ***broadcast (shared wire or medium)***
  - old-fashioned Ethernet
  - 802.11 wireless LAN

shared wire (e.g.,  
cabled Ethernet)

shared RF  
(e.g., 802.11 WiFi)

shared RF  
(satellite)

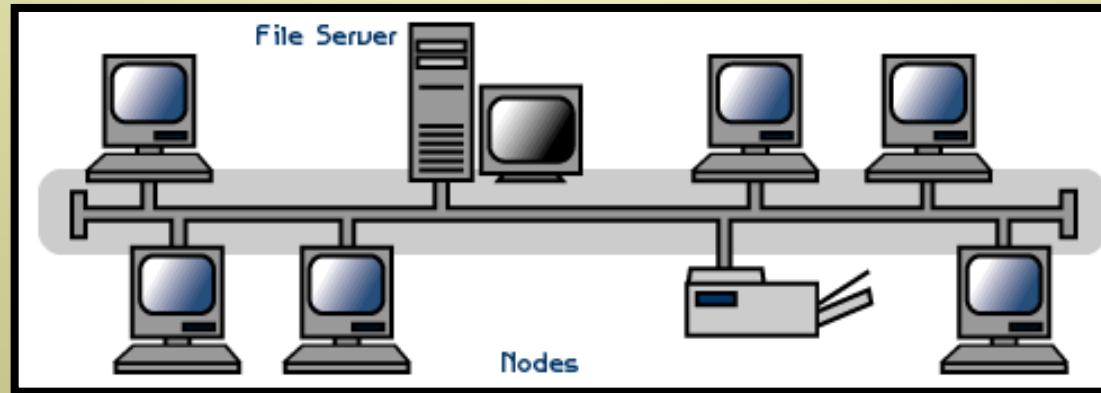

humans at a  
cocktail party  
(shared air, acoustical)

# Network topologies

- ❖ a network is a system connecting different devices
- ❖ the connection strategy to connect these devices is referred to as **Network Topology**
- ❖ the best topology depends on the network needs
- ❖ possible network topologies are:
  - Common Bus Topology
  - Star Topology
  - Ring Topology
  - Fully Connected Topology
  - Tree Topology
  - Combined Topology

# Common bus topology

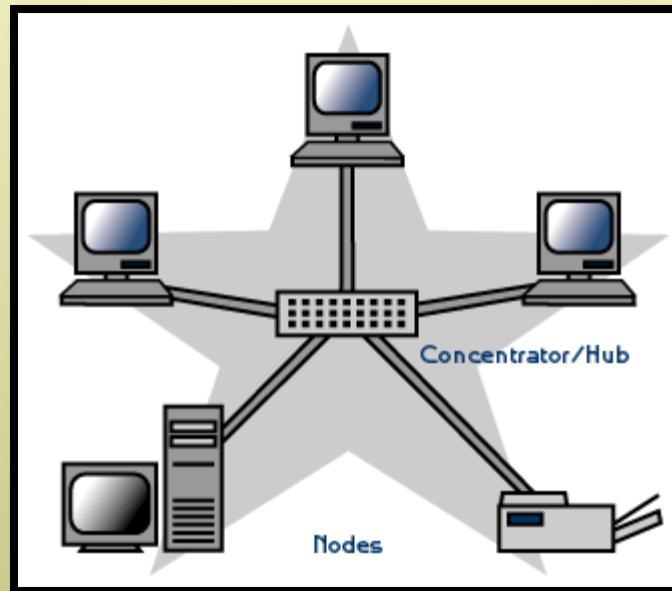

- ❖ simply known as ***Bus Topology*** or ***Linear Bus Topology***
- ❖ **terminators** are placed at both ends

# Common bus topology

---

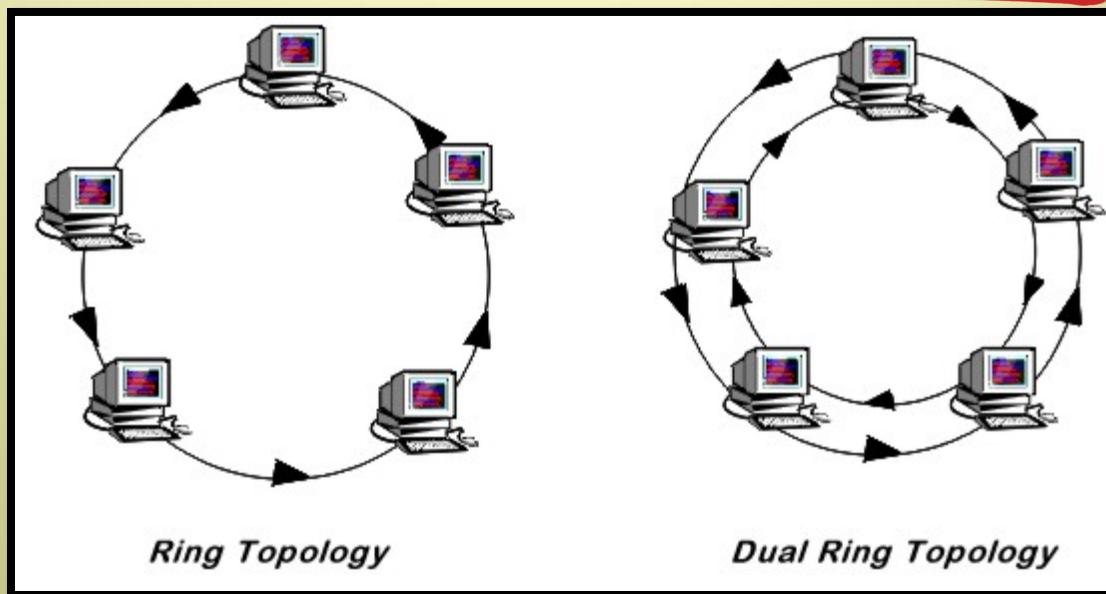

- ❖ collision is possible
- ❖ a collision results on *noise*
- ❖ the interfaces detect the noise on the bus, stop transmission, wait for a random amount of time then attempt transmission again
- ❖ this process is called **Carrier Sense Multiple Access with Collision Detection (CSMA/CD)**
- ❖ the **Ethernet** (original configuration) is an example of a common bus network
- ❖ Advantages?
- ❖ Disadvantages?

# Star Topology

- ❖ the central component is commonly called **hubs** or **switches**
- ❖ Advantages?
- ❖ Disadvantages?

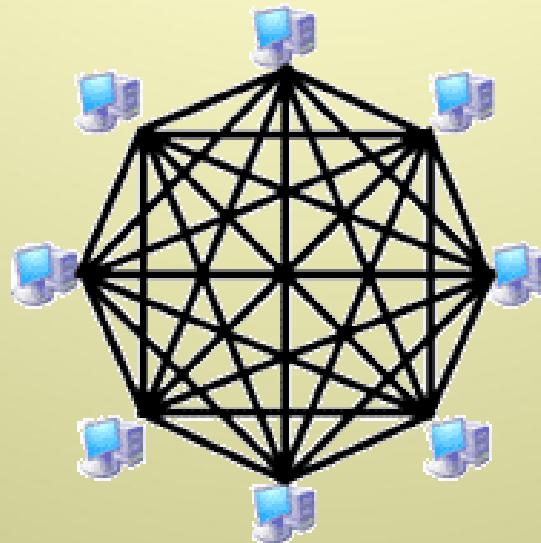

# Ring Topology

- ❖ the ring can either be **unidirectional** or **bidirectional (dual)**
- ❖ IBM's **Token Ring** network is an example of a ring topology, where a token (sequence of bits) is passed between the devices.
- ❖ Advantages?
- ❖ Disadvantages?

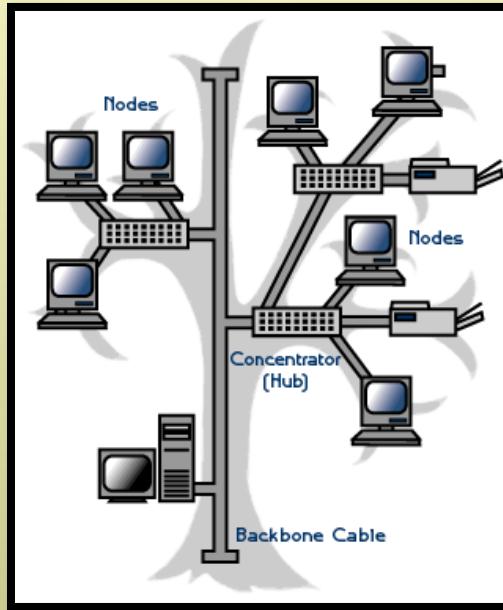

# Fully-Connected Topology

---

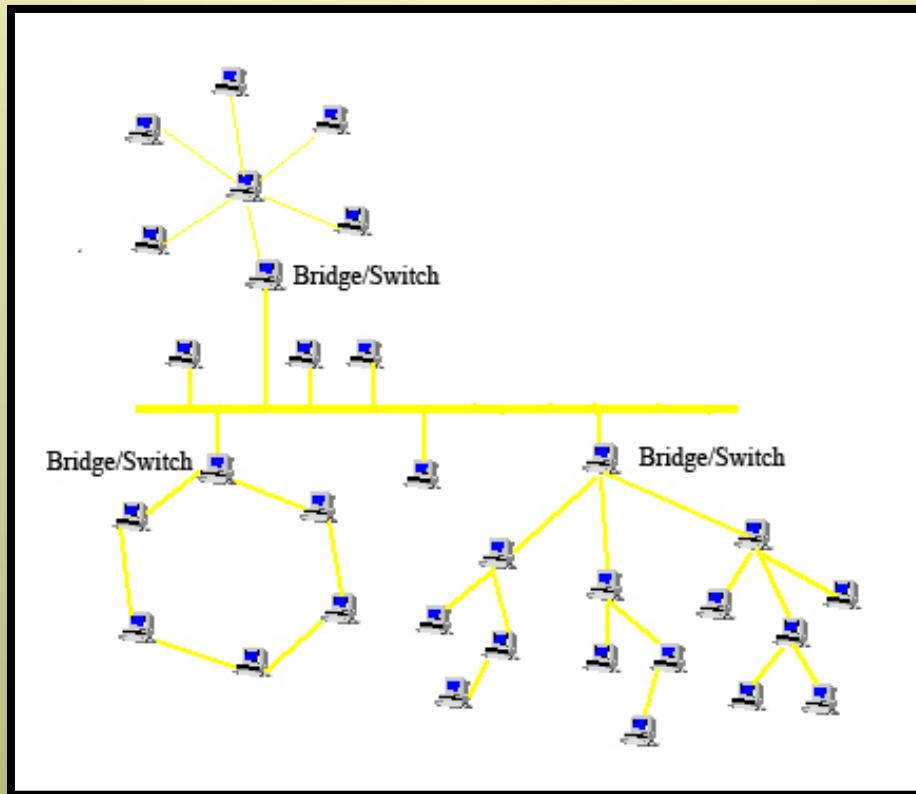

- ❖ a direct link is there between each pair of devices in the network; this design is extreme
  
- ❖ Advantages?
- ❖ Disadvantages?

# Tree Topology

- ❖ combines characteristics of linear bus and star topologies
- ❖ allows for the expansion of an existing network
  
- ❖ Advantages?
- ❖ Disadvantages?

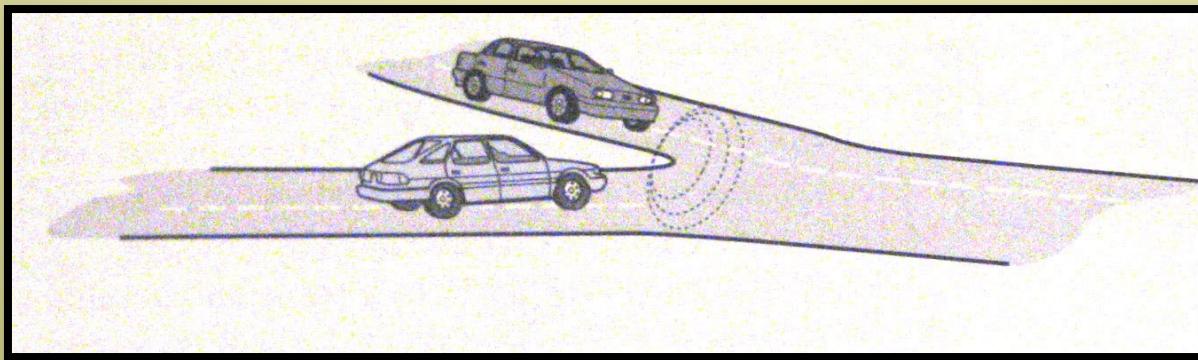

# Combined topologies

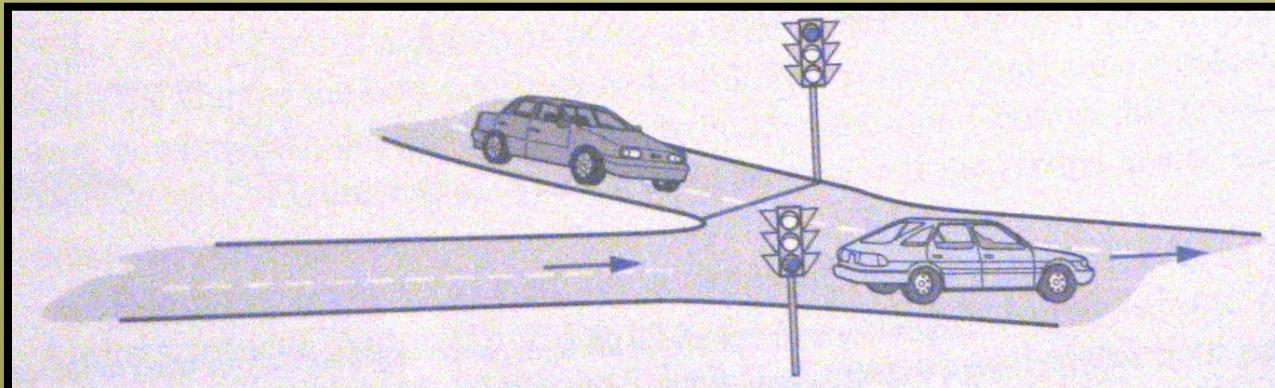

- ❖ used by many computer networks
- ❖ groups of specialized users may need to have a separate LAN
- ❖ different LANs are connected through bridges/switches

# Contention protocols

- ❖ access to the medium from many entry points is called contention
- ❖ unless controlled, contention may lead to fatal problems
- ❖ contention protocols are used to avoid such problems

No Contention Protocol

Stop-and-Go Access Protocol

# Multiple access protocols

- ❖ single shared broadcast channel
- ❖ two or more simultaneous transmissions by nodes: interference
  - **collision** if node receives two or more signals at the same time

## *multiple access protocol*

- ❖ distributed algorithm that determines how nodes share channel, i.e., determine when node can transmit
- ❖ communication about channel sharing must use channel itself!
  - no out-of-band channel for coordination

# An ideal multiple access protocol

*given:* broadcast channel of rate  $R$  bps

*desiderata:*

1. when one node wants to transmit, it can send at rate  $R$ .
2. when  $M$  nodes want to transmit, each can send at average rate  $R/M$
3. fully decentralized:
  - no special node to coordinate transmissions
  - no synchronization of clocks, slots
4. simple

# MAC protocols: taxonomy

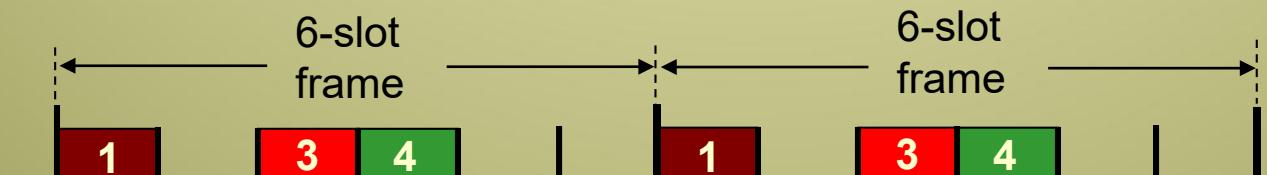

three broad classes:

- ❖ *channel partitioning*
  - divide channel into smaller “pieces” (time slots, frequency, code)
  - allocate piece to node for exclusive use
- ❖ *random access*
  - channel not divided, allow collisions
  - “recover” from collisions
- ❖ *“taking turns”*
  - nodes take turns, but nodes with more to send can take longer turns

# Channel partitioning MAC protocols: TDMA

## TDMA: time division multiple access

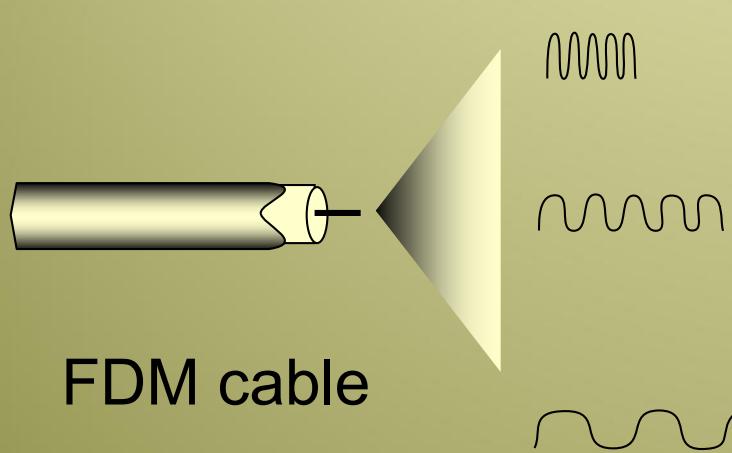

- ❖ access to channel in "rounds"
- ❖ each station gets fixed length slot (length = pkt trans time) in each round
- ❖ unused slots go idle
- ❖ example: 6-station LAN, 1,3,4 have pkt, slots 2,5,6 idle

# Channel partitioning MAC protocols: FDMA

## FDMA: frequency division multiple access

- ❖ channel spectrum divided into frequency bands
- ❖ each station assigned fixed frequency band
- ❖ unused transmission time in frequency bands go idle
- ❖ example: 6-station LAN, 1,3,4 have pkt, frequency bands 2,5,6 idle

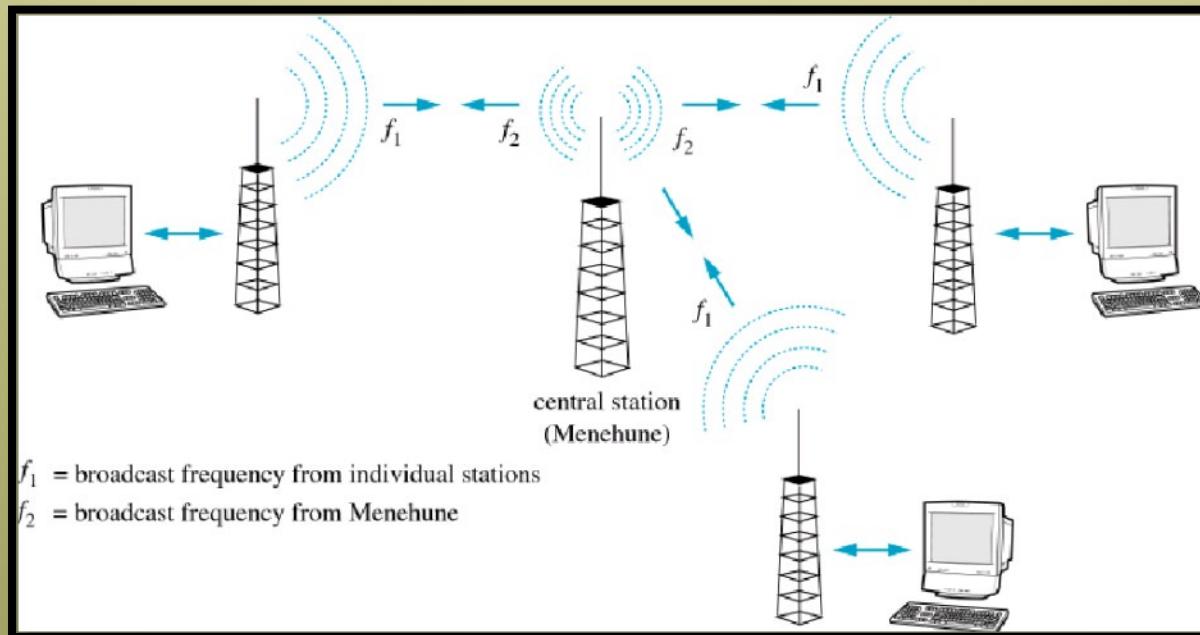

# Random access protocols

- ❖ when node has packet to send
  - transmit at full channel data rate R.
  - no *a priori* coordination among nodes
- ❖ two or more transmitting nodes → “collision”
- ❖ random access MAC protocol specifies:
  - how to detect collisions
  - how to recover from collisions (e.g., via delayed retransmissions)
- ❖ examples of random access MAC protocols:
  - ALOHA
  - slotted ALOHA
  - CSMA, CSMA/CD, CSMA/CA

# ALOHA protocols

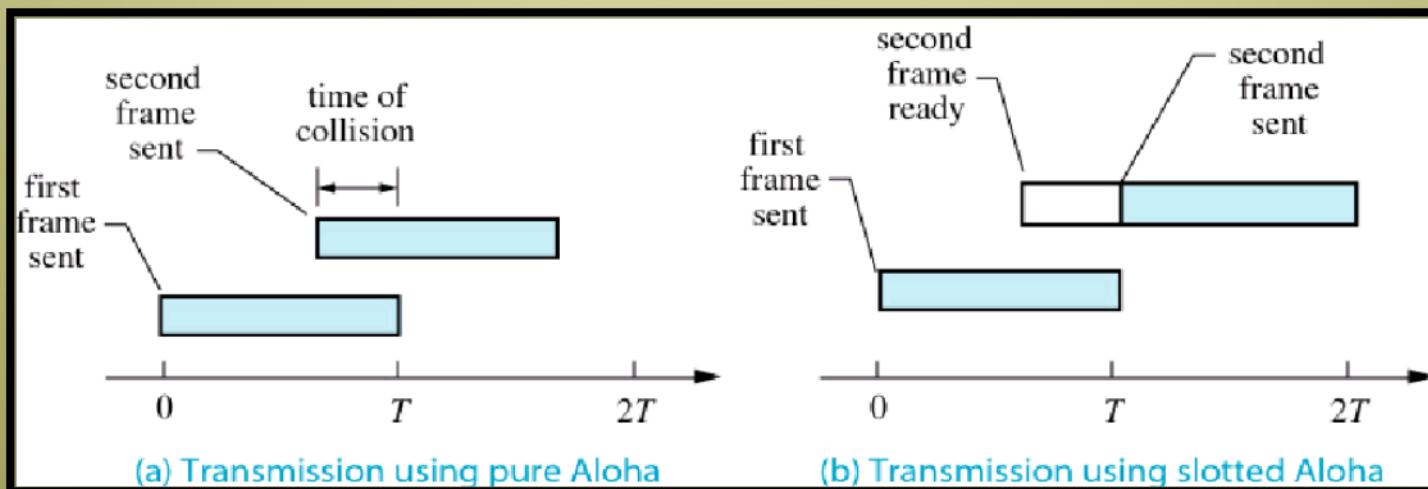

- ❖ earliest contention protocol in 1970s by Univ. of Hawaii, called **Pure ALOHA**
- ❖ several stations to central station (Menehune) by radio communication
- ❖  $f_1$  for broadcast,  $f_2$  (different frequency than  $f_1$ ) for ACK
- ❖ any station can transmit; if collision then wait random time

Aloha System

# Slotted ALOHA

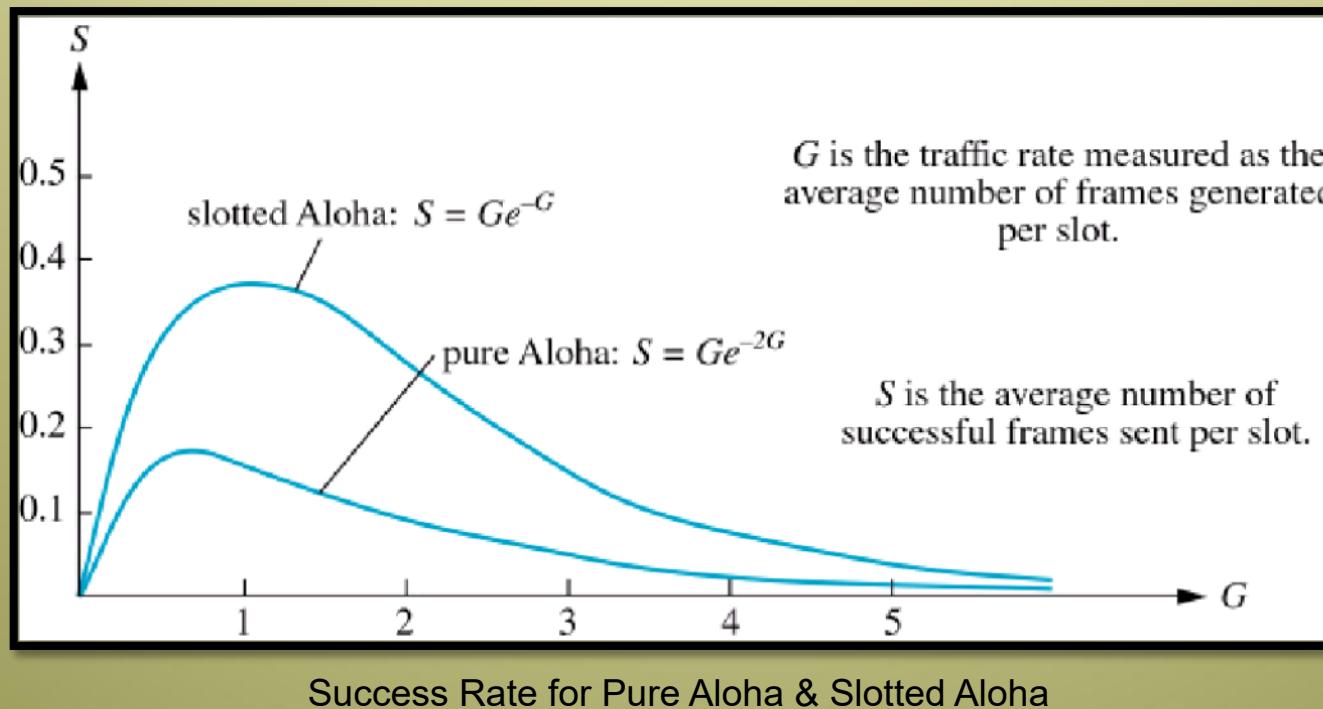

- ❖ any overlap in signals, even a small one, would force retransmission
- ❖ hence, a minimal safe period to transmit two signals is  $2T$  ( $T$  is time period)
- ❖ so, to allow a device to transmit, you should reserve  $2T$  for that
- ❖ not to waste such time, Slotted Aloha is used
- ❖ devices can only send at the beginning of each slot

Transmission Using Pure Aloha & Slotted Aloha

# Slotted ALOHA: efficiency

- ❖ Slotted Aloha has a higher success rate than Pure Aloha
- ❖ however, with increased traffic, the difference may not be that significant

# Carrier Sense Multiple Access (CSMA)

**CSMA:** listen before transmit:

if channel sensed idle: transmit entire frame

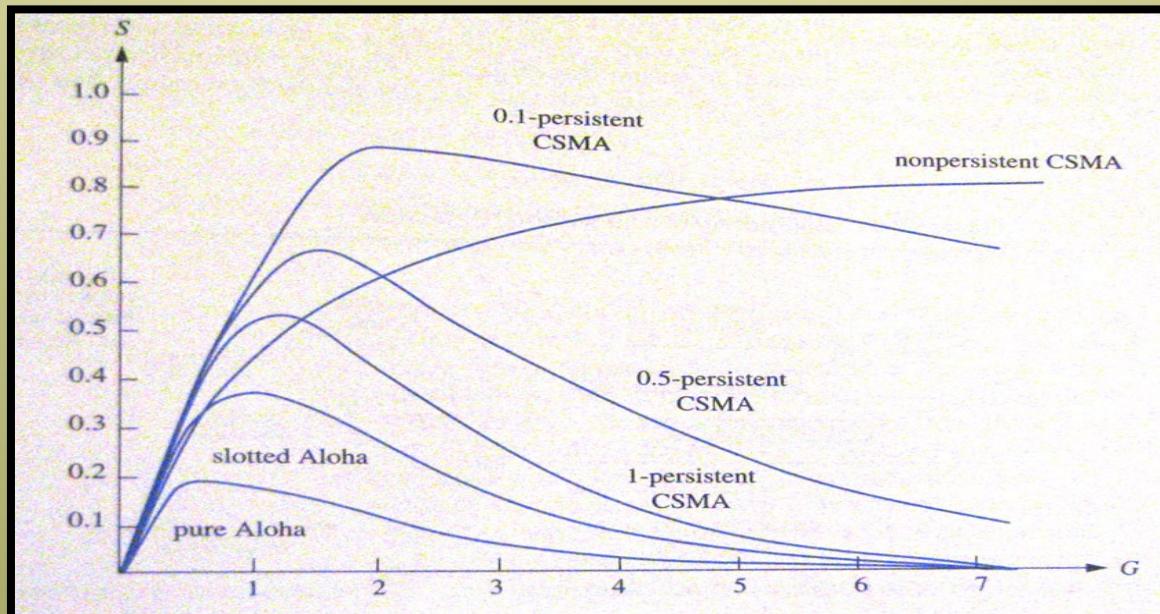

❖ if channel sensed busy, defer transmission

❖ human analogy: don't interrupt others!

# Carrier Sense Multiple Access (CSMA)

## **Carrier Sense Multiple Access Protocols (CSMA)**

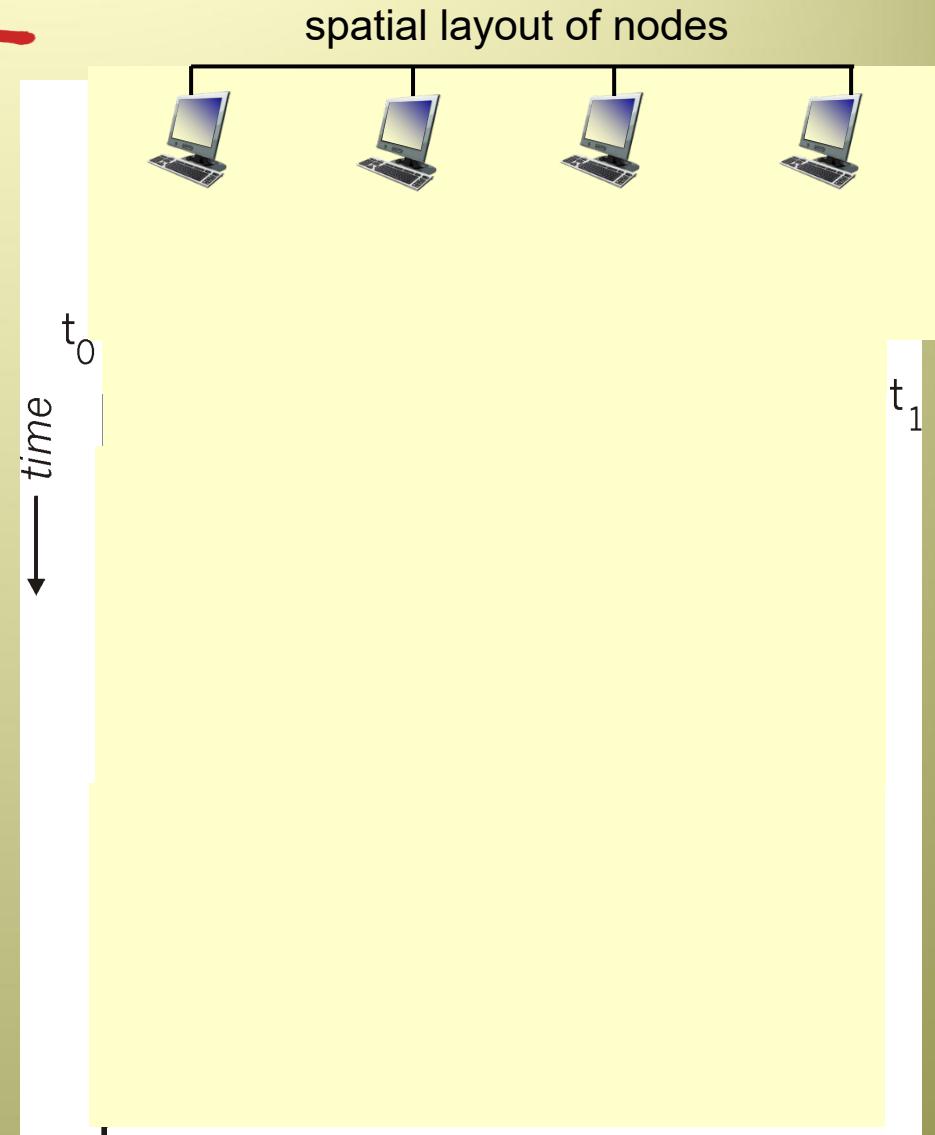

- ❖ sense the medium at the beginning of a slot, send if the medium is free, else wait for next slot
- ❖  **$p$ -persistent CSMA:**
  - Continue to sense the active medium
  - If free, send with a probability  $p$  ( $0 < p \leq 1$ )
  - ❖  $p=0$  never transmits (wait again) ;
  - ❖  $p=1$  always transmits (collision chances are higher)
- ❖ **Nonpersistent CSMA:** check periodically, if free send else wait for one time slot and check again

Success Rate for CSMA & Aloha Protocols

# CSMA collisions

- ❖ **collisions can still occur:** propagation delay means two nodes may not hear each other's transmission
- ❖ **collision:** entire packet transmission time wasted
  - distance & propagation delay play role in determining collision probability

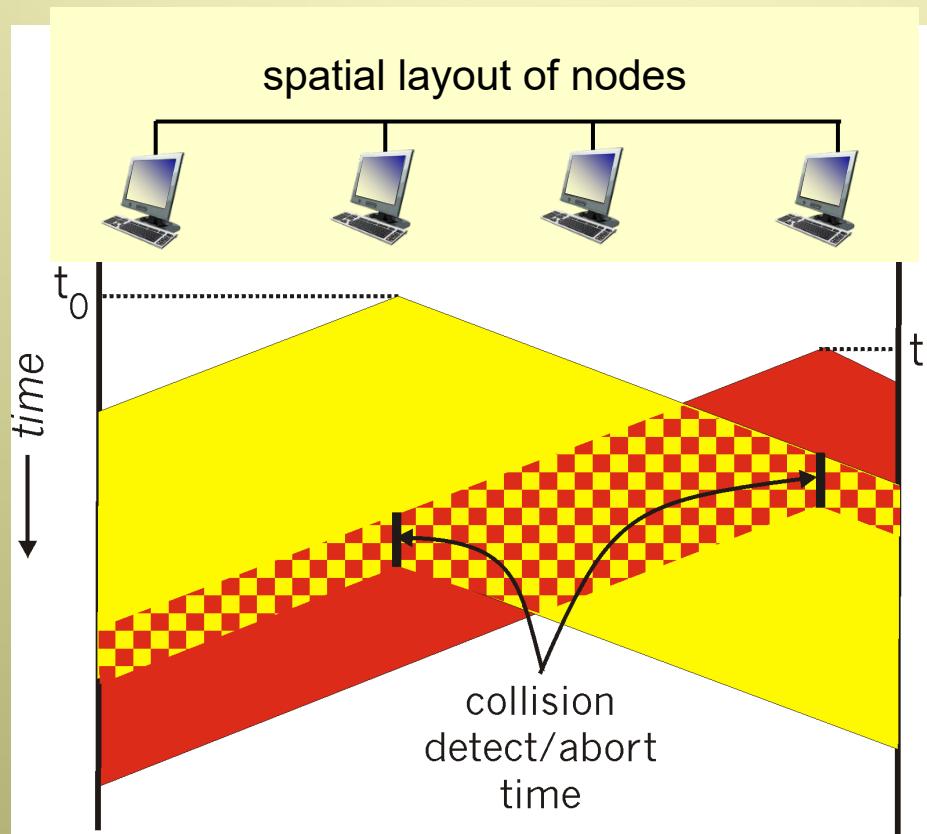

# CSMA/CD (Collision Detection)

**CSMA/CD:** carrier sensing, deferral as in CSMA

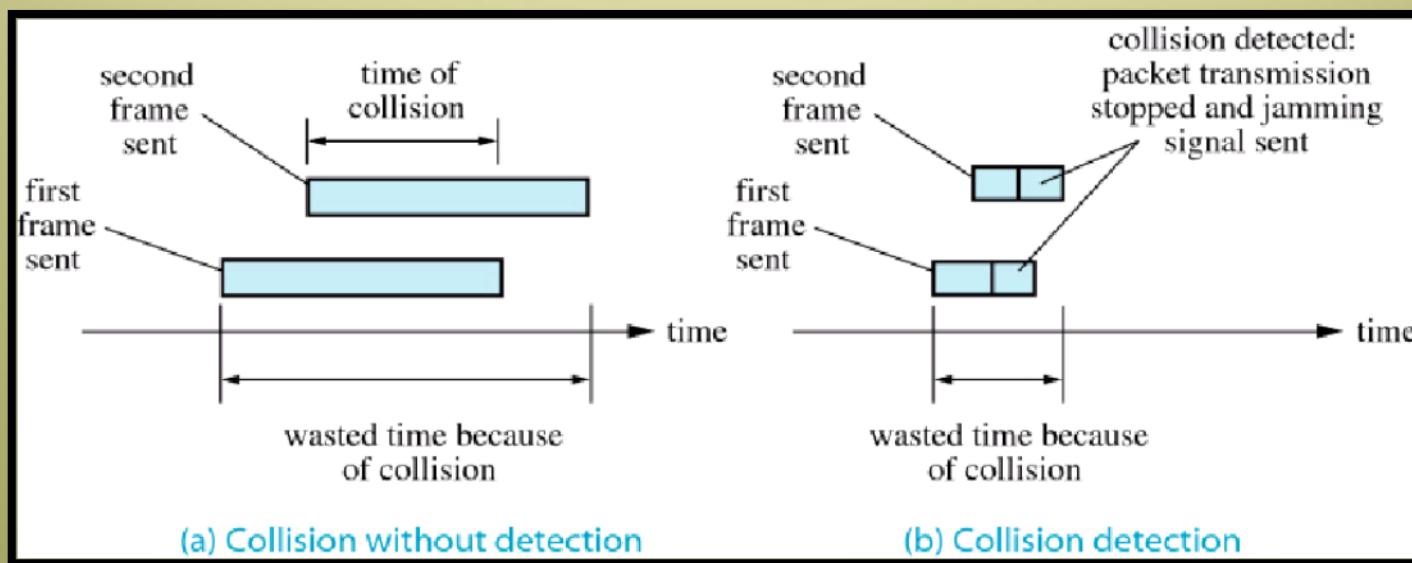

- collisions detected within short time
  - colliding transmissions aborted, reducing channel wastage
- 
- ❖ collision detection:
    - easy in wired LANs: measure signal strengths, compare transmitted, received signals
    - difficult in wireless LANs: received signal strength overwhelmed by local transmission strength
  - ❖ human analogy: the polite conversationalist

# CSMA/CD (collision detection)

# Collision detection (CD)

- ❖ instead of sending entire frame then discover that collision has occurred when no ack is received, sense the medium for collision and stop transmitting if occurs
- ❖ this will avoid the medium from being unusable during collision
- ❖ Commonly used with CSMA – *called CSMA/CD*

Collision with and without Detection

# Collision detection (CD)

- ❖ two issues worth considering:
  - frame size
  - distance
- ❖ frame size:
  - the frame has to be of a minimum size so the device can detect collision before it finishes
  - if too large, a device can monopolize the medium
  - so, how small should a frame be?
    - depends on the maximum time it takes to detect collision

# Collision detection (CD)

Example: Assume:

- *10 Mbps bit rate,*
  - *Largest distance between two devices is 2 KM*
  - *Signal propagate at a rate of 200 meter/ $\mu$ sec*
- To propagate 2 KM it takes 10  $\mu$ sec
- To propagate 4 KM (worst case, go & come back), we need 20  $\mu$ sec
- Rate of 10 Mbps is the same as 10 bits each  $\mu$ sec
- In 20  $\mu$ sec we have 200 bits or  $200/8 = 25$  bytes
- This is the minimum size a frame can be so CD can be made

# Collision detection (CD)

- ❖ the other issue with CD is *distance*
- ❖ for example CD does not work well with satellite since the time needed to travel back and forth between ground and satellite is too big due to the large distance

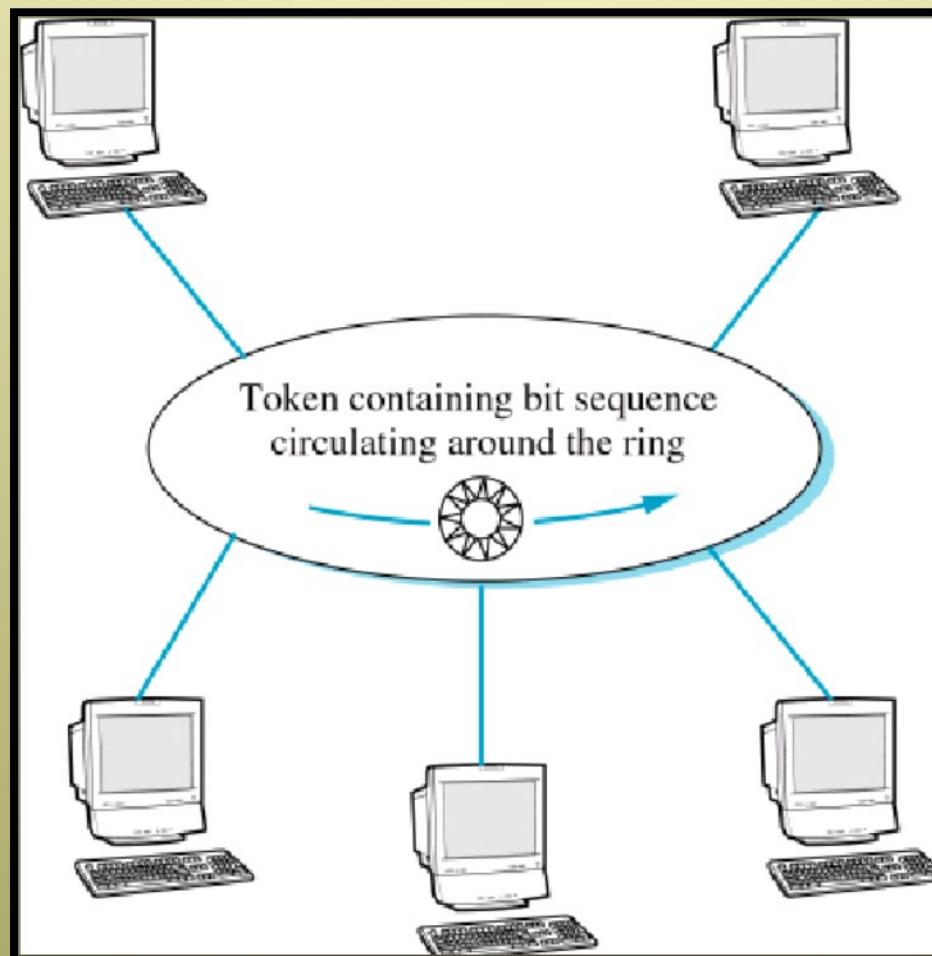

## **Binary exponential back-off algorithm**

- ❖ varies the waiting time before sending again if collision occurred
- ❖ if first collision then wait 0, or 1 slots
- ❖ second collision then wait randomly for 0, 1, 2, or 3 slots
- ❖ .....
- ❖ .....
- ❖ if  $n$  successive collisions then wait for random # of slots between 0 and  $2^n - 1$ , when  $n > 16$  give-up and signal to higher layer!

# Token passing

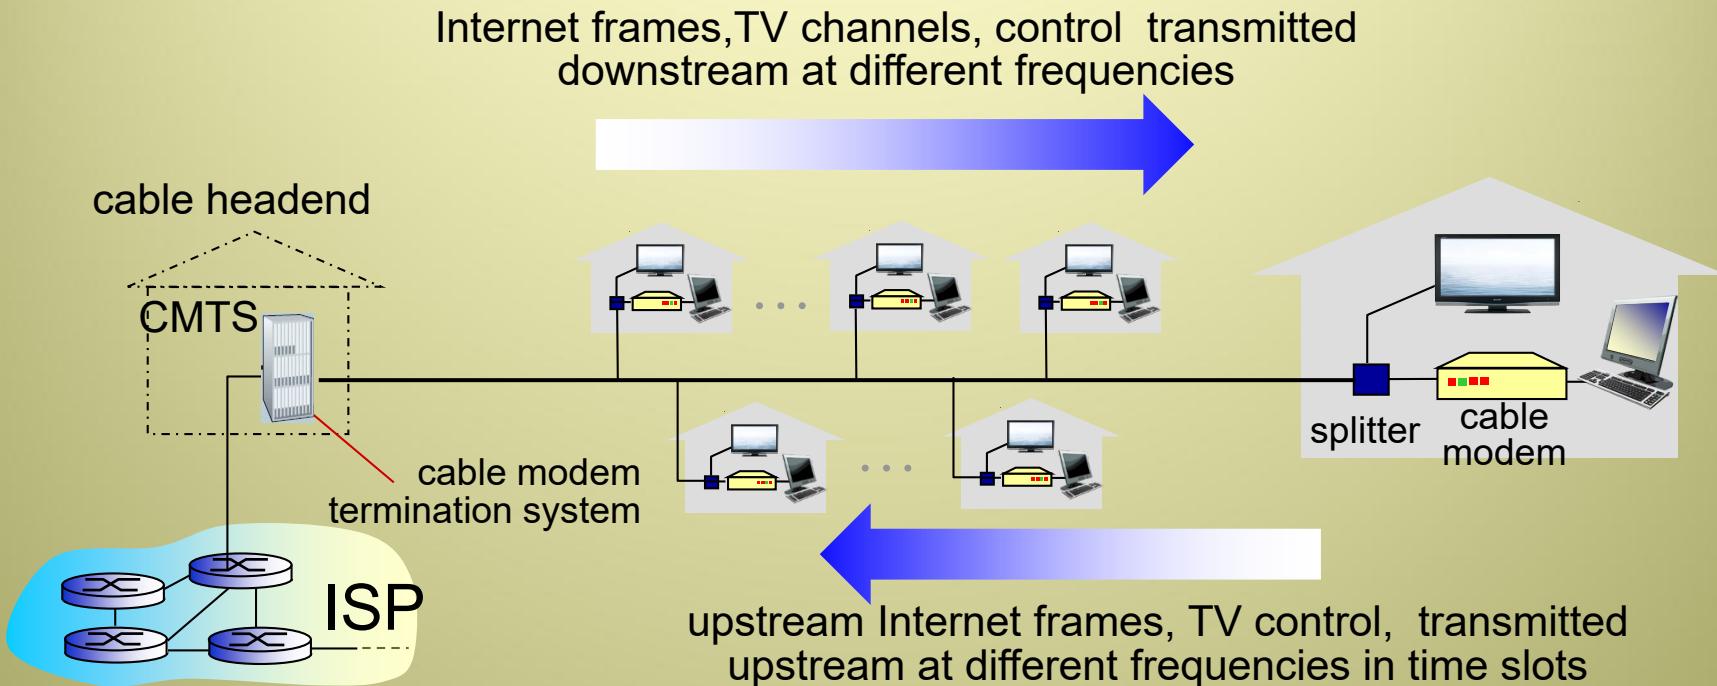

- ❖ instead of sending whenever it wishes, a device will take turns in sending with the other ones
- ❖ capture token to send data frame
- ❖ if data then remove token and transmit data frame; else pass token to neighbor
- ❖ only sender can put the token back on ring after receiving it back
- ❖ one frame per token
  
- ❖ advantage: contention is much controlled than the previous protocols
  
- ❖ Disadvantages:
  - All devices must be known
  - Complexity (what happen if the token is lost or if the device that has control over it fails)

# Token passing

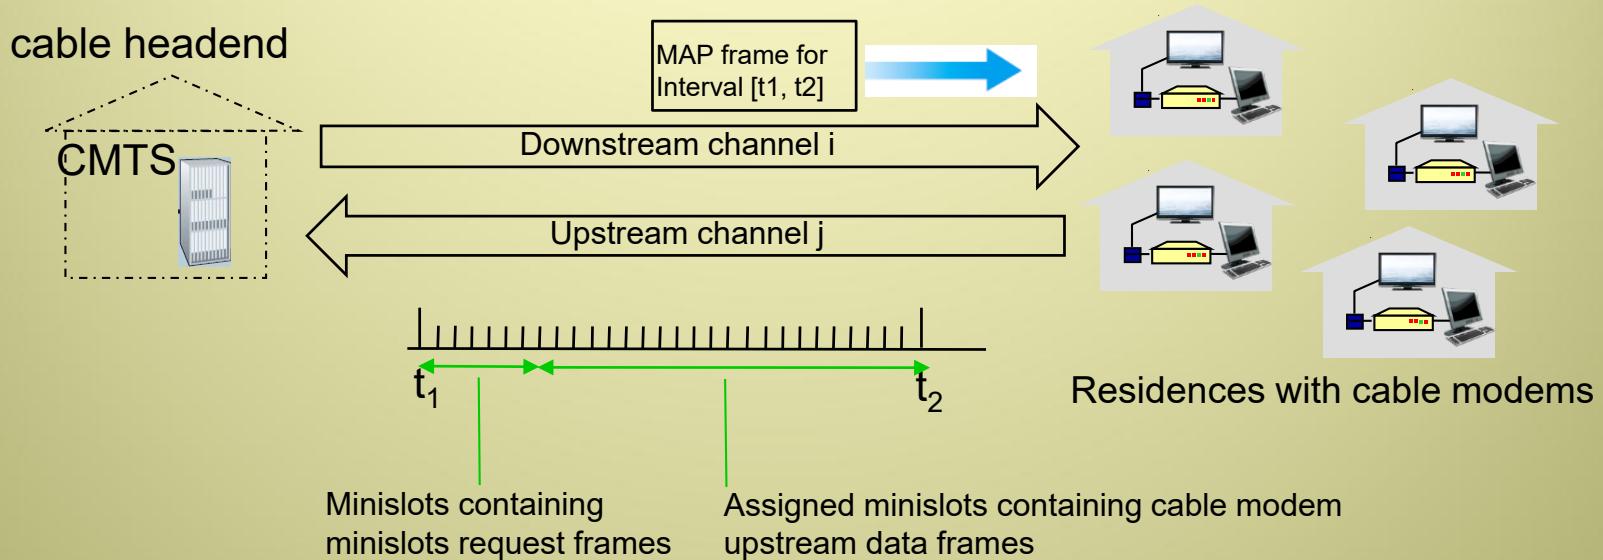

Token Ring Network

# Cable access network

- ❖ **multiple** 40Mbps downstream (broadcast) channels
  - single CMTS transmits into channels
- ❖ **multiple** 30 Mbps upstream channels
  - **multiple access:** all users contend for certain upstream channel time slots (others assigned)

# Cable access network

## DOCSIS: data over cable service interface spec

- ❖ FDM over upstream, downstream frequency channels
- ❖ TDM upstream: some slots assigned, some have contention
  - downstream MAP frame: assigns upstream slots
  - request for upstream slots (and data) transmitted random access (binary backoff) in selected slots

# Error correction

- ❖ when errors are detected, either resend the message or correct it
- ❖ in many cases correction will be a much better choice
- ❖ 1 parity bit check → 2 possibilities  
whether or not an error occurred; but not where
- ❖ 2 parity bit checks → 4 possibilities of failures and successes
- ❖ 3 parity bit checks → 8 possibilities of failures and successes
- ❖  $n$  parity bit checks →  $2^n$  possibilities of failures and successes

# Error correction

- ❖ how many *single-error* possibilities are there in the a 3-bit string, for example  $m_1 m_2 m_3$ ?
- ❖ 1 parity check → whether or not an error occurred, but not where – Not enough to correct
- ❖ 2 parity checks → 4 possibilities
  - Example: Assume **I 0 I** is sent and there are P1 & P2 parity checks
  - P1 is even parity for  $m_1$  &  $m_2$ ; P2 is even parity for  $m_1$  &  $m_3$
  - P1 is hence set to 1, P2 is set to 0. Assume also that parities are delivered successfully!
  - Possible deliveries with a maximum of a single-bit error are:
    - **0 0 I** → P1 fails, P2 fails
    - **I I I** → P1 fails, P2 succeed
    - **I 0 0** → P1 succeed, P2 fails
    - **I 0 I** → P1 succeed, P2 succeed → No error in transmission
  - As the receiver, can you correct the error?

# Error correction – Hamming Codes

## **Hamming Codes**

- ❖ Hamming code requires the insertion of few parity bits in the bit stream before sending it
- ❖ the parity bits check the parity in strategic locations
- ❖ if bits are altered, the receiver will examine the combinations of failures to discover where the errors are

# Error correction – Hamming Codes

## **Hamming Codes – *Single-bit Error Correction***

- ❖ how many *single-error* possibilities are there in an 8-bit string, for example  $m_1 \ m_2 \ m_3 \ m_4 \ m_5 \ m_6 \ m_7 \ m_8$ ?
- ❖ 3 parity checks *would* be enough to discover a single error in one of 8 positions, however
- ❖ errors may also occur in the parity bits
- ❖ 4 parity checks are needed  $\rightarrow 2^4 > 12$

# Error correction – Hamming Codes

## Hamming Codes – *Single-bit Error Correction*

- ❖ in general, must have  $n$  parity checks, where  $2^n$  is larger than the bits sent

$n$ (parity checks)	Bits sent	Success/fail possibilities
1	9	2
2	10	4
3	11	8
4	12	16 (enough to cover the 13 possible events – no error or single-bit error in one of 12 positions)

# Error correction – Hamming Codes

## Hamming Codes – *Single-bit Error Correction*

- ❖ Which positions will parity checks cover? Where are they inserted?

Data to send:	$m_1$	$m_2$	$m_3$	$m_4$	$m_5$	$m_6$	$m_7$	$m_8$				
Hamming code:	$p_1$	$p_2$	$m_1$	$p_3$	$m_2$	$m_3$	$m_4$	$p_4$	$m_5$	$m_6$	$m_7$	$m_8$

# Error correction – Hamming Codes

## **Hamming Codes – Single-bit Error Correction**

- assume 4-bit binary number,  $b_1 \ b_2 \ b_3 \ b_4$ , where  $b_i = 0$  if the parity  $p_i$  succeed, and 1 otherwise

Error Position	Binary $b_4, b_3, b_2 \ \& \ b_1$	Parity P <sub>1</sub> / Position	Parity P <sub>2</sub> / Position	Parity P <sub>3</sub> / Position	Parity P <sub>4</sub> / Position
0 (No Error)	0000				
1	0001	1			
2	0010		2		
3	0011	3	3		
4	0100			4	
5	0101	5		5	
6	0110		6	6	
7	0111	7	7	7	
8	1000				8
9	1001	9			9
10	1010		10		10
11	1011	11	11		11
12	1100		Link Layer A	12	12

# Error correction – Hamming Codes

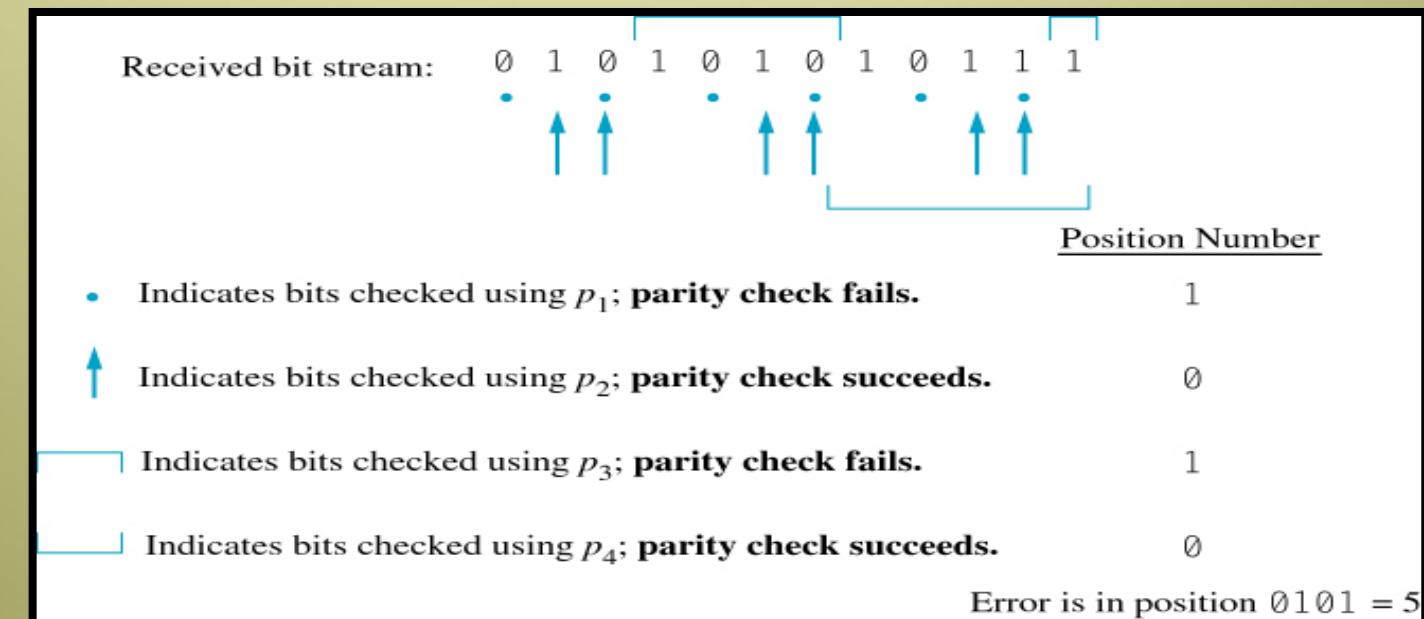

## Hamming Codes – *Single-bit Error Correction*

Example:

Bit Stream  
Before  
Transmission

Data:		0	1	1	0	0	1	1	1		
$m_1$	$m_2$	$m_3$	$m_4$	$m_5$	$m_6$	$m_7$	$m_8$				
<b>Hamming code:</b>											
$p_1$	$p_2$	$m_1$	$p_3$	$m_2$	$m_3$	$m_4$	$p_4$	$m_5$	$m_6$	$m_7$	$m_8$

Parity Checks  
of Frame After  
Transmission

# Error correction – Hamming Codes

## **Hamming Codes – *Multiple-bit Error Correction***

- ❖ a more general Hamming code for multiple-bit error do exist
- ❖ the number of extra parity bits becomes much larger in this case
- ❖ when there are many possible codes, a reduction is needed in order to analyze them quickly
- ❖ code Correlation can be used to achieve such reduction
- ❖ when you have two, or more, Hamming codes, a Hamming distance is defined as the minimum number of bit changes that can lead one code to be detected as another
- ❖ a Radius is defined as Hamming Distance / 2

# Error correction – Hamming Codes

## **Hamming Codes – *Multiple-bit Error Correction***

- ❖ Example:

**Note:** This topic is a major subject of higher-level/graduate courses. It is **not** a part of this course and you will **not** be examined on it. This example is just to give an extra knowledge on the subject.

Code 1	Code 2	Code 3
1	0	1
0	1	1
0	1	0
1	0	0

- ❖ the codes have a minimum Hamming Distance of 2, or a Radius of 1
- ❖ a code such as 0100 (which is not among the exact valid codes) can be coded as either code 3 with a missing first bit, or as code 2 with a missing third bit
- ❖ a change of 2 bits may lead to two codes to be identical; or in other words decoded incorrectly (for example if code 3 changed to **0110**, it will be decoded incorrectly as code 2)
